## **1.0 VOLUME I ACCREDITATION SUPPORT PACKAGE DESCRIPTION**

Five distinct accreditation support activities contribute to the information provided in ASP-I: definition of the model's configuration management baseline; summarization of model assumptions, limitations and errors; determination of the model's verification and validation (V&V) status and usage history; assessment of available documentation; and assessment of software quality. Each of these activities is described in greater detail below.

### **1.1 CONFIGURATION MANAGEMENT BASELINE**

The CM baseline description for a model provides prospective users with an indication of how well the model is controlled and supported. Models with poorly defined configurations and unspecified (or vague) change control procedures are likely to produce inconsistent results across the spectrum of users and applications, with the consequence that model predictions will not be highly regarded. Models whose configurations are well specified, and whose change procedures are well disciplined are more likely to have timely supporting documentation and to produce consistent, well accepted results. Moreover, well managed models have a lower risk of failing detailed V&V aimed at higher levels of accreditation.

The CM baseline for a model consists of a description of the model, its development history, current version status (including documentation), applicable change procedures, model development policy (including beta site version integration), and any configuration management policies, procedures, guidelines and support functions in place for the model. Taken as a whole, these information elements provide the prospective user with a vantage point from which to assess the discipline with which a model has been developed, the important operational differences between extant versions, and the potential impact of model management discipline on the acceptability of model results. As such, CM baseline information is essential to the basic choice of a model for further V&V or accreditation for a specific application. The CM Baseline for SWEG is found in Section 2.

### **1.2 SUMMARY OF ASSUMPTIONS, LIMITATIONS AND ERRORS**

Different users typically have different applications for the same model and these usually require that the model have certain characteristics. This section of ASP-I will help the user determine, at an early stage, whether or not the model's assumptions, limitations and errors place it outside the realm of applicability to the problem at hand. Coupled with the model's usage history, the summary of assumptions, limitations and errors can be a powerful model selection tool. This summary also provides a method for integrating any assumptions, limitations, and errors discovered during previous V&V efforts, and for incorporating any that may be discovered in future V&V efforts by other users. A summary of assumptions, limitations, and errors for SWEG is in Section 3.

### **1.3 V&V STATUS AND USAGE HISTORY**

Supporting evidence for model acceptability is given by a documented V&V audit trail, indicating that the user community has enough interest in the model to conduct such efforts. Evidence for such activity may be sparse, however, given that emphasis on V&V as part of

the model credibility problem is of recent vintage. It is possible, therefore, that the primary criterion by which a prospective user will judge the suitability of the model for a particular application will be community acceptance, as indicated by the model's usage history. As V&V becomes de rigueur for modeling and simulation (M&S), however, the range of applications for which model results are supported by V&V will become broader, offering a clearer picture of the degree to which model results can be trusted on the basis of prior uses of the model. Information on the V&V status and usage history of SWEG can be found in Section 4.

## **1.4 DOCUMENTATION ASSESSMENT**

This section reviews the current status of a model's documentation with respect to standards developed for the verification of mature M&S. The standards were developed by reviewing MIL-STD-498, DOD-STD-2167A (2168), Joint Technical Coordinating Group for Aircraft Survivability (JTCG/AS) and service-specific policies, procedures and guidelines relating to M&S development, and tailoring these standards to the problem of "V&V in reverse" for mature M&S. The results of these efforts are set forth in [3] and [4], which specify the number, format, and content of a minimum documentation set acceptable for rational use of model results, and efficient conduct of verification and validation.

In general, a well documented model will be supported by a documentation set consisting of a User's Manual, a Programmer's Manual, an Analyst's Manual, and a Software Design Document (or its equivalent). Each of these documents should contain certain information specific to its function as specified in [1] and [2]. The documentation assessment task reviews each available component of model documentation for completeness and compliance with the recommended standards. Discrepancies are noted, implications for model use and V&V are summarized, and recommendations for improvement of the documentation are provided. The documentation assessment applicable to the model is normally found in Section 5; however, documentation assessment was outside the scope of the task order under which this document was prepared.

## **1.5 SOFTWARE QUALITY ASSESSMENT**

This section gives the prospective model user an indication of the conformance of model code to accepted software development and documentation practice. The structure of the source code of a given model is analyzed from a software engineering perspective in three major areas: use of programming standards; computational efficiency; and memory utilization. Within each of these major areas are several contributing factors which are individually evaluated and aggregated into a "score" representing an overall evaluation of source code quality.

Software quality assessment is no substitute for actual model experience and application as developed by a user community. It does, however, focus the user community on clearly identifiable software problems in a structured way, and gives the prospective model user a feeling for the trade-off between software "maturity" and credible model use. The results of the software quality assessment of SWEG would normally be found in Section 6; however, software quality assessment was outside the scope of the task order under which this document was prepared.
